

Questions:

1. Were you able to include these changes?

I was able to include the changes by adding additional entities to my diagram that allowed for the customers new additions to be added in the most efficient and correct way.

2. Notice any opportunities to use weak entity types? What hinted you?

I saw the opportunity to create a weak entity type with the creation of the Listing_Details entity. This entity is completely dependent on the fact that

3. Notice any opportunities to use associative entity types? What hinted you?

When she mentions the owner to property relationship, she adds that they need to store ownership details. This entity type depends on the owner owning a property and the property having an owner, so it is the perfect spot for an associative entity.

4. Based on your diagram, can a property listing update the price twice within the same day?

Yes, this is because the relationship between listing and listing details is one to many. That means that one listing can have 1 or many listing details. Also, since the deduction time is a datetime type it stores all the date details down to the second so that the data is not overwritten

5. Based on your diagram, do you know who is the current owner of each property? Does your diagram support historical information about property ownership?

Yes, we are able to keep track of the current owner via the entity named owner which links them to the property. The historical information is tracked via the associative entity in between the property and owner which tracks the ownership start and end date and owner percentage.

6. What is the identifier of the offer in your diagram? Does your diagram cover the possibility that the same client may make multiple offers for the same property, within the same day? What would you change to include that?

The identifier of offer in my diagram is offer date, which is stored as a date time, which stores it all the way down to the second. This allows the client to make multiple offers on same property all within the same day and was at the company's request but It is also identified by Offer_Id so that each offer has a different ID associated with it.

7. How would your diagram change if a property could be managed by multiple offices at the same time (e.g., regional or co-listings)? Which relationship(s) would be affected?

I changed the diagram to allow for a property to be managed by multiple offices by making the relationship between property and sales offices many to many. So, each sale

office lists 0 or many properties. Each property is listed by one or many sales offices. I also had to change the relationship from employee to property so that 1 or many employees could be the listing agent for a property.
